Control statements allows to customize the execution trace at run-time:

- if
- while
- for
- ...

They are implemented through *jumps*:

- special instructions
- allow to select the next instruction to execute at run-time

# Where to Jump? I

Control in  
ACSE

Alessandro  
Barengi,  
Ettore  
Speziale,  
Michele  
Tartara

ACSE is a syntax-directed translator:

- instructions emission constrained by source code ordering

But jumps are specials:

## Forward jump

## Backward jump

# Where to Jump? II

Control in  
ACSE

Alessandro  
Barengi,  
Ettore  
Speziale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

## Forward jumps:

- conditionals, loop exits
- when we generate the jump we only know that we must jump (jump target not yet emitted)

## Backward jumps:

- found in loops
- when we generate the jump we know where to jump (we have already emitted the code where we want to jump)

# Where to Jump? III

Control in  
ACSE

Jumps

While  
Statement

Advice

Bibliography

To address jump translation:

- physical address vs logical location

*Labels* represent logical locations.

## Addresses

Consider a `while` statement containing 4 instructions:

**physical address** 4 instructions after loop head

**logical address** the statement following the loop

# Labels

Control in  
ACSE

Bibliography

The `axe_engine.h` contains APIs for label management:

## Label management APIs

Function	Meaning
<code>newLabel</code>	create a label
<code>assignLabel</code>	bind a label to a logical address <sup>1</sup>
<code>assignNewLabel</code>	combined operation

Binding to physical addresses performed by ACSE.

---

<sup>1</sup>Fixing.

# Exploiting Labels

Control in  
ACSE

Alessandro  
Barenghi,  
Ettore  
Speziale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

Two scenarios:

## Forward jump

- 1 create a label *lbl* when a jump is needed
- 2 jump to *lbl*
- 3 fix *lbl* when the corresponding statement is reached

## Backward jump

- 1 create and fix label at jump target
- 2 emit jump to *lbl* when the jump statement must be generated

# Fall-through Path

Control in  
ACSE

Alessandro  
Barengi,  
Ettore  
Speciale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

Usually branches have two outgoing edges:

**jump** points to the label associated with the jump instruction

**fall-through** points to the next statement

## Branch paths

# A Real Control Structure I

Control in  
ACSE

Alessandro  
Barenghi,  
Ettore  
Speciale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

Consider the while statement:

while grammar rule

while\_statement:

```
WHILE LPAR exp RPAR code_block;
```

What we have:

Naked while

What we would have:

Theoretical flow

# A Real Control Structure II

Barengi,  
Ettore  
Speziale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

Once `exp` has been evaluated we can:

- exit the loop
- enter the loop

We need a *conditional jump* to handle such case:

- two paths: taken and not taken

At the end of the `code_block` we need to re-evaluate the loop condition:

- unconditional branch to `exp` evaluation

All what we need is **emitting jumps**!

# While Layout I

Control in  
ACSE

Alessandro  
Barengi,  
Ettore  
Speciale,  
Michele  
Tartara

Introduction

Jumps

**While  
Statement**

Advice

Bibliography

By reserving spaces for jumps the code layout is:

## Code segment layout

# While Layout II

Control in  
ACSE

Speziale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

Edges targets three instructions:

- the fall-through edge is implicit
- can be eliminated
- we need only two labels

## Removing useless labels

# While Layout III

Control in  
ACSE

Alessandro  
Barengi,  
Ettore  
Speciale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

Since the BEQ jumps predicates over the zero bit, we must enforce its evaluation:

exp is an immediate

exp is an intermediate

# While Sources

Control in  
ACSE

Alessandro  
Barengi,  
Ettore  
Speziale,  
Michele  
Tartara

Introduction

Jumps

While  
Statement

Advice

Bibliography

The `exp` type is known at compile-time:

- `while_statement` customization performed at compile-time

On sources (`Acse.y`):

- lookup the `while_statement` rule
- the `WHILE` token is *typed*

We need:

- an action in the middle to generate the loop exit jump
- an action to generate the backward jump and marking the statement end label

Introduction

Jumps

While  
Statement

Advice

Bibliography

All programming languages are built around few simple constructs:

- those not present in ACSE can be found in the test

Better to type rules related to complex constructs:

- keep code clean!

Try starting with a scheme:

- to get an overview
- some minds work better with pictures

Do not redo work:

- read the ACSE headers
- some code already present (e.g. `collections.h`)
